

Cleaner traffic, deeper product use, but conversion is not yet proven

Tue 18 - Mon 24 August 2026 vs Tue 11 - Mon 17 August 2026

Fresh report generated and persisted

The Worker completed `/run` at **2026-08-25 15:40:35 UTC**. The subsequent `/latest` request returned the same timestamp, confirming the report was written to D1. Today is excluded because current-day GA4 data is partial.

The useful signal is below the WAF mix shift. Organic acquisition grew, app usage deepened, and more users reached full company profiles. Commercial intent remains a small-sample signal: 7 users viewed a paid item and 3 users fired `begin_checkout`. No sequential cohort or purchase result is available in this payload.

HEADLINE METRICS

SESSIONS 215 +7.5% raw	USERS 142 -4.7% raw	PAGEVIEWS 849 +87.0%
KEY EVENTS 522 +207.1%	ENGAGEMENT 62.3% +13.8 pp raw	AVG SESSION 9:43 +168.3%

Bot-adjusted estimate

Assuming China traffic represents the bot population and the prior week contained about 71 such sessions: human sessions are roughly **129 -> 187 (+45%)**, human users **78 -> 114 (+46%)**, and engagement is **75.2% -> 71.7% (-3.5 points)**. Average human session duration still rises from about **5:37 to 11:10**. These are estimates, not GA4 readings.

Verdict: audience quality and product depth appear materially better. The data does not yet prove a stronger paid conversion rate, and several dimensioned totals need reconciliation before precise shares are used.

Sessions per day. Amber marks the three days before the post-WAF pattern becomes visible; blue marks the lower-volume period. Daily rows sum to 217 while the headline total is 215, so this chart is directional rather than a reconciled ledger.

CHANNEL	SESSIONS	PRIOR	CHANGE	USERS	ENGAGEMENT	KEY EVENTS
Organic Search	130	88	+48%	71	79.2%	325
Direct	76	107	-29%	64	34.2%	135
Unassigned	15	0	new	9	0%	55
AI Assistant	3	5	-2	3	100%	6
Cross-network	2	0	new	2	100%	1

Organic Search is the strongest acquisition result. It rose from 88 to 130 sessions and carries the highest meaningful engagement rate. The comparison is useful because it is within the same dimension and query definition; its exact share of all sessions is not reliable because the channel rows sum to 226, not 215.

Direct remains contaminated by traffic mix. Its 29% decline and low engagement are consistent with bot removal, but 28 China sessions and a suspicious 19 sessions from 19 US users remain. Geography-by-channel data is needed before calling Direct clean.

Unassigned is a measurement warning. Fifteen sessions report zero engagement but 55 key events. This does not by itself prove a checkout redirect caused the issue. A channel-by-landing-page cross-tab is required before adding Unassigned and empty landing-page sessions or assigning a cause.

Reconciliation warning

Headline sessions = **215**; daily session rows = **217**; channel/source rows = **226**; session_start events = **211**. These may reflect GA4 metric and dimension semantics, but the report must explain them before presenting exact traffic shares.

CONTENT AND ENTRY POINTS

PAGE	VIEWS	USERS	AVG ENGAGED	READING
/app + /app/	405	65*	2:56	core product
/	169	78	0:18	turnstile
/es + /es/	101	22*	0:52	strong intent
/es/buscar-administradores-empresas/	25	10	0:41	strong entry
/due-diligence variants	15	7*	0:08	low depth
/spanish-company-due-diligence/	7	4	0:10	new
/pricing	6	2	0:11	new
/spanish-company-register-search/	6	7	0:04	regressed

* User counts are summed across slash variants and can double-count the same user. The combined engagement figure is duration divided by the summed user counts, so it carries the same limitation.

LANDING PAGE	SESSIONS	BOUNCE	KEY EVENTS
/	71	46.5%	128
/app	41	14.6%	206
/es	21	14.3%	85
empty string	17	88.2%	16
(not set)	15	80.0%	0
/es/buscar-administradores-empresas	10	0%	32
/spanish-company-register-search	6	50.0%	4

The app is doing the work. The two app paths produced 405 views and long engagement, while the homepage remains a routing surface. This supports investment in graph activation and direct app entry rather than treating homepage time as the primary content KPI.

Spanish intent pages remain the clearest content opportunity. /es retained 18 of 21 landing sessions, and the Spanish administrator-search page recorded 10 landings with zero bounces. The samples are small, but the same pattern has repeated across several windows.

The English register-search page needs inspection. Six landing sessions, 50% bounce, four seconds of engagement and four key events all move in the wrong direction. Check recent template, intent and performance changes before producing more pages from that pattern.

Commercial surfaces remain lightly visited: 28 combined views across pricing and due-diligence pages, about 3.3% of all pageviews before accounting for overlap.

PRODUCT STAGE REACH - NOT A SEQUENTIAL FUNNEL

Each row counts distinct users who fired that event. The Worker does not prove that the same users moved through adjacent rows in order, so the percentages are reach indicators, not conversion rates.

Profile exploration is the strongest product signal. Full-profile users rose from 7 to 18 and profile CTA users from 2 to 7. Those counts are real stage audiences; the apparent 90% node-to-profile and 39% profile-to-CTA ratios are not cohort conversions until user-level event sequence is queried.

Commercial intent exists but is not yet clean. Seven users fired `view_item`. Three users generated 18 `begin_checkout` events, an average of six per user. That pattern could mean repeated attempts, duplicate instrumentation, validation failures or comparison activity. Query `checkout_failed` and `checkout_redirect` alongside `purchase` before interpreting it as demand.

What to instrument next

Build a true user-sequence funnel with ordered event intersections; collect `view_item` -> `begin_checkout` -> `checkout_redirect` -> `purchase`; and report users as well as event counts. Explicitly query `purchase` instead of relying on a top-25 event table, where a low-volume `purchase` can be omitted.

Device signal: mobile produced 36 sessions at 75.0% engagement versus 178 desktop sessions at 59.6%. The post-WAF mix makes this more credible than last week, but 36 sessions remain too few for a redesign decision.

ACTIONS AND FRIDAY DELIVERY

PRIORITY	ACTION	WHY NOW
1	Verify Friday Cron Event and new D1 timestamp	Proves scheduled trigger, not just /run
2	Reconcile session totals across dimensioned queries	Prevents false channel shares
3	Build a sequential paid funnel	Separates stage reach from conversion
4	Audit repeated begin_checkout events	18 events from 3 users may be friction
5	Cross-tab Unassigned with landing page and checkout	Tests the attribution hypothesis
6	Keep expanding Spanish intent pages	Best repeated entry-page signal

Where this PDF is placed

Today's PDF is written to `output/pdf/mapasocietario-weekly-analytics-2026-08-18-to-2026-08-24.pdf` inside the mapasocietario repository.

What Friday's cron actually places

The Cloudflare Worker does **not** generate a PDF. At 14:30 UTC on Friday it pulls GA4, then upserts JSON into the D1 table `analytics_weekly`. The latest stored payload is exposed by the authenticated `/latest` endpoint. A separate renderer or scheduled assistant must turn that payload into a PDF and deliver it.

Friday success criteria - 28 August 2026

1. Cloudflare Cron Events shows a successful invocation near **14:30 UTC / 16:30 Madrid**.
2. `/latest` has a new `generatedAt` near that time without calling `/run` manually.
3. The current period is **2026-08-21 to 2026-08-27**; the prior period is **2026-08-14 to 2026-08-20**.
4. D1 contains the new period row and Worker Logs contain no scheduled pull error.

If a PDF should appear automatically every Friday, that delivery step still needs to be implemented. The clean design is: Worker cron -> D1 JSON -> report renderer -> PDF storage/delivery. Choose the destination explicitly: repository artifact, R2 bucket with a private link, email, or an assistant task attachment.
